A family farm meets multiple needs of the household

Eco-farming addresses hunger, poverty and climate change

Olivier De Schutter

Agriculture must be redirected to environmentally sound, socially just production methods to address the food and energy crises, hunger, poverty and climate change, reports Olivier De Schutter, Special Rapporteur to the UN on the right to food. Agroecology, which mimics natural processes, has had remarkable successes in the past decade, improving incomes and livelihoods for many millions of the world’s poorest, small-scale farmers and has improved the resilience of food systems. Supporting small-scale farmers to make the transition to agroecology worldwide is vital to avoid more food and climate disasters in the 21st century. This article is abridged from the report, ‘Agroecology and the right to food’.

Small-scale farmers can double food production within 10 years using ecological methods, a UN report shows. In a comprehensive review of recent scientific literature, the study calls for a fundamental shift to agroecology to boost food production and improve millions of the poorest people’s livelihoods. ‘Industrial farming on large plantations will not solve hunger or stop climate change. The solution lies in supporting small-scale farmers’ knowledge and in raising their incomes so as to contribute to rural development. To feed 9 billion people in 2050, we urgently need to adopt the most efficient farming techniques available,’ says Olivier De Schutter, UN Special Rapporteur on the right to food and author of the report presented to the Human Rights Council of the UN in January 2011.
The report shows that agroecological methods out-perform chemical fertilizers, boosting food production in difficult environments. Hunger today is caused by poverty rather than lack of global food supplies. After the food price crisis of 2008, it's necessary to reorient agriculture to highly productive methods that preserve ecosystems and invest in those who need it most, poor, small-scale farmers. Higher incomes for smallholders increase demand for goods and services from local traders, whereas large estates spend more on imported inputs and machinery. Support for small producers, breaks the vicious cycle of rural poverty and expanded urban slums where poverty breeds poverty.

It is widely cited that agricultural production must increase by 70% by 2050 if present consumption patterns persist. Already nearly half the world’s cereal production is used for animal feed, and meat consumption is predicted to increase from 37.4 kg/person/year in 2000 to over 52 kg/person/year by 2050. The United Nations Environmental Programme (UNEP) estimates that the calories lost by using cereals for meat production instead of directly for human food could meet the annual calorie needs of more than 3.5 billion people. Reallocating cereals to human consumption, is desirable in developed countries where excess animal protein consumption contributes to ill health. Agrofuel production also diverts crops from food needs to energy needs, bringing more pressure on agricultural supplies. Policies to reduce these diversions could greatly contribute to meeting the growing need for food. Climate change with more frequent and extreme drought and floods and less predictable rainfall is already affecting the capacity of some communities to feed themselves, and is destabilising markets. Agricultural production is threatened in entire regions, particularly those dependent on rain-fed agriculture. By 2080, 600 million additional people could be at risk of hunger, as a direct result of climate change. In Sub-Saharan Africa, arid and semi-arid areas are projected to increase by 60 million to 90 million hectares, and in Southern Africa, it’s estimated that yields from rain-fed agriculture could be halved between 2000 and 2020.

Agroecology applies ecological science to agricultural systems, mimicking natural processes. It enhances soil productivity, diversifies crops, and protects crops against pests, using natural methods, beneficial trees, plants, animals and insects. It increases farm productivity and food security, improves incomes and rural livelihoods, and reverses the trend towards species loss and genetic erosion.

**Agroecology raises yields**

A wide range of agroecological techniques have been developed and proven in various regions. *Integrated nutrient management* fixes nutrients from inorganic and organic sources within the farm system and reduces nutrient loss by controlling erosion. *Agroforestry* incorporates multifunctional trees in agricultural systems. Large-scale agroforestry projects have successfully rehabilitated land in several countries including Tanzania, Malawi, Mozambique and Zambia.

*Water harvesting* in dryland areas allows abandoned and degraded lands to be cultivated. In West Africa, stone barriers built beside fields reduce runoff during the rainy season, improving soil moisture, replenishing water tables, and reducing soil erosion. The water retention capacity is multiplied five to ten-fold and biomass production 10 to 15 times. Livestock can feed on the grass that grows along the stone barriers after the rains. *Integration of livestock into farming systems* provides a protein source for the family and nutrients are returned to the soil by dairy cattle, pigs and poultry and by fish or shrimps raised in irrigated rice fields or ponds.

Such resource-conserving, low-external-input techniques have significantly improved yields. A systematic study of these techniques used in 286 recent sustainable agriculture projects in 57 poor countries on 37 million hectares, found average crop yield increases of 79% and improved supply of critical environmental services. Reanalysis of the same data by UNEP and UNCTAD found that in Africa the increase was even higher than this global average; a 116% increase for all African projects and a 128% increase for projects in East Africa.

Research commissioned by the UK’s Foresight Global Food and Farming Futures project came to the same conclusions. It reviewed 40 projects in 20 African countries where sustainable intensification was developed during the 2000s. They included crop improvement, particularly breeding of neglected plants and cultivars, integrated pest management, soil conservation and agro-forestry. By early 2010, these projects had improved around 12.75 million hectares of land with documented benefits for 10.39 million farmers and their families. Average crop yields more than doubled over a period of 3-10 years, bringing an increase in food production equivalent to 557 kg per farming household.
Even seemingly minor innovations can bring high returns. In Kenya, researchers and farmers developed the ‘push-pull’ strategy to control weeds and insect pests. This ‘pushes’ pests away by inter-planting the corn crop with insect-repellent plants like *Desmodium*, while ‘pulling’ them towards small plots of Napier grass, a plant that excretes a sticky gum which both attracts and traps pests. The system has other benefits: *Desmodium* can be used as fodder. The strategy doubles maize yields and milk production while improving the soil and has been widely adopted in East Africa, taught through town meetings, national radio broadcasts and farmer field schools. In Japan, farmers found that ducks and fish were as effective as pesticides in controlling insects in rice paddies, also providing additional protein for their families. The ducks eat weeds, weed seeds, insects, and other pests, reducing hand-weeding labour, while duck droppings provide plant nutrients. The system has been adopted in China, India, the Philippines and in Bangladesh where the International Rice Research Institute reports 20% higher yields and 60% increase in net incomes.

**Reduces rural poverty**

Agroecology helps increase incomes in rural areas by promoting on-farm fertility generation, which reduces farmers’ reliance on external inputs and state subsidies, making vulnerable smallholders less dependent on moneylenders. Livestock manure and growing green manures can supply nutrients to the soil and farmers can also establish a ‘fertilizer factory in the fields,’ planting trees that take nitrogen out of the air to ‘fix’ it in their leaves which later fertilise the soil. *Faidherbia albida*, a nitrogen-fixing acacia species indigenous to Africa and widespread over the continent, sheds its foliage during the early rainy season when field crops are being established, so does not compete much for light, nutrients or water in the growing season. It markedly increases maize yields especially in conditions of low soil fertility and avoids dependence on synthetic fertilizers, their costs being increasingly high in recent years. In Zambia, unfertilised maize yields near *Faidherbia* trees averaged 4.1 t/ha, compared to 1.3 t/ha just beyond the canopy. Comparable techniques, like use of leguminous cover-crops to fix nitrogen also have huge potential, particularly for the poorest farmers, least able to afford fertilizers. Costs of importing and distributing fertilizers are the main reason for very low fertilizer use in low-income sub-Saharan African countries.

Following the dramatic food crisis due to drought in 2004-2005, Malawi launched a fertilizer subsidy programme in 2005-2006 but is now introducing agroforestry and nitrogen-fixing trees to prepare for the time when fertilizer subsidies will be scaled back or withdrawn. By mid 2009, over 120,000 Malawian farmers had received training and tree materials from the programme, and support from Ireland has now enabled extension to 40% of the country benefiting 1.3 million of the poorest people. Agroforestry has been able to increase maize yields from 1 t/ha to 2–3 t/ha, even if farmers cannot afford commercial nitrogen fertilizers and to more than 4t/ha with a quarter-dose of mineral fertilizer. This offers a strategy to exit synthetic fertilizer subsidy schemes, linking subsidies directly to agroforestry investments on the farm, thus improving the efficiency of fertilizer use, providing long-term sustainability in nutrient supply and building soil health to sustain crop yields. Malawi is exploring this ‘subsidy to sustainability’ approach.

Agroecological approaches can be labour-intensive initially due to the complexity of managing different plants and animals on the farm, and recycling the waste produced. Yet creating employment may be an advantage in rural areas of developing countries, where under-employment and population growth is high. It would slow urbanisation which is overloading public services in these countries, contribute to rural development and preserve the ability of following generations to meet their needs. The cost of creating jobs in agriculture is often significantly lower than in other sectors. Peasant organizations report that agroecology is also more attractive to farmers working on the land for long hours, with shade from trees and absence of smell and toxic chemicals.

In Burkina Faso, instead of migrating, work groups of young men specialised in land rehabilitation techniques, go from village to village to help farmers improve the land. Farmers are now buying degraded land to improve and paying labourers to build structures such as ‘zai pits’ that can retain water and transform yields. Over 3 million hectares of land in Burkina Faso is now rehabilitated and productive.

Agroecological approaches are compatible with gradual mechanization of farming. Machinery required for techniques such as no-till and direct seeding, bring more jobs, particularly in Africa which increasingly manufactures simple equipment. Employment can also come from agroforestry expansion when tree nurseries are run as a business. Funded by the World Agroforestry Centre, the Malawi Agroforestry Food Security Programme set up 17 nurseries that raised 2,180,000 seedlings in its first year.

**Improves nutrition**

The Green Revolution focused primarily on boosting cereal crops. While over 80,000 plant species are available to humans, rice, wheat and maize now supply the bulk of our food needs. But, they are mainly carbohydrate sources, with relatively little protein, and few other nutrients essential for adequate diets. The shift from diversified cropping systems to simplified cereal-based systems has contributed to micronutrient malnutrition in many developing countries. Nutritionists increasingly insist on the need for more diverse agricultural production to ensure a more diversified nutrient supply. The diversity of species on farms following agroecological principles, and in urban or peri-urban agriculture, is an important source of vitamins and other micronutrients. Indigenous fruits contribute around 40% of the natural food-basket that rural households rely on in southern Africa.

**Mitigates climate change**

Agroecology improves resilience to climate change, and more extreme weather events. After Hurricane Mitch in 1998, a study of 180 communities of smallholders in Nicaragua demonstrated that farming plots cropped with simple agroecological methods - rock bunds and terracing, green manure, crop rotation, mulch, legumes, trees, plowing parallel to the slope, noburn, live fences,
and zero-tillage - had on average 40% more topsoil, higher field moisture, less erosion and lower economic losses than conventional farms. On average, agroecological plots lost 18% less arable land to landslides and had 69% less gully erosion than conventional farms.

More frequent and severe droughts can be expected in the future. The agroforestry programme developed in Malawi has protected farmers from crop failure after droughts. On-farm experiments in Ethiopia, India, and the Netherlands have demonstrated that soils on organic farms improve the drought resistance of crops. Diversity of species and farm activities involved in agroecology also helps mitigate risks from new pests, weeds and diseases. The agroecological practice of cultivar mixture bets on genetic diversity in fields to improve disease resistance. In Yunnan Province in China, after disease-susceptible rice varieties were planted mixed with resistant varieties, yields improved by 89% and rice blast disease was 94% less severe than when they were grown in monocultures.

Agroecology puts agriculture on the sustainable path, freeing food production from reliance on fossil energy. It mitigates climate change by increasing carbon sinks of soil organic matter and above-ground biomass, and avoids carbon dioxide emissions by reducing direct and indirect energy use on farms. The Intergovernmental Panel on Climate Change (IPCC) has estimated the global mitigation potential for agriculture at 5.5 to 6 Gt of CO2-equivalent yearly by 2030. Most of this (89%), is from increased carbon sequestration in soil organic matter (humus), as occurs with agroecology.

**Disseminating practices**

Agroecology is knowledge-intensive, requiring development of both ecological literacy and decision-making skills in farmer communities. Modern science combines with local knowledge in agroecological research. Farmer participation is crucial for agroecological practices to succeed. So far, agroecology has been developed by grassroots organizations and NGOs, and has spread through farmer field schools and farmers’ movements, such as the Campesino movement in Central America. Experience with agroecological techniques is growing every day in peasant networks such as La Via Campesina and the AgriCultures Network, Réseau des Organisations Paysannes et des Producteurs Agricoles de l’Afrique de l’Ouest (ROPPA), Eastern & Southern Africa Farmers’ Forum (ESAFF), and PELUM (Participatory Ecological Land Use Management) network in Africa, MASIPAG network in the Philippines (Magsasaka at Siyentista Tungo sa Pag-unladng Agrikultura), or Assessoria e Serviços a Projetos em Agricultura Alternativa (AS-PTA) and Movimento dos Trabalhadores Sem Terra (MST) in Brazil. These organisations are already functioning as learning organizations and must now be supported with investments in this role to disseminate their knowledge widely.

Participation empowers the poor, a vital step in poverty alleviation. Specific schemes for women can balance the greater access men have to formal agricultural knowledge. Co-operatives can help achieve economies of scale, and connecting sustainable farms to fair markets is important. But agroecology will fail to achieve the desired results unless markets are managed to protect farmers from volatile prices and local markets from the dumping of subsidised products. Fiscal incentives, market structures and credit and land tenure policies must be aligned with the need to move to agroecological methods.

Investing maximum available resources in sustainable agriculture is essential for future food security and to achieve responsibilities taken on by States on the right to food. Investments in agroecological research should be prioritised, because of the considerable potential of such practices. States need long-term policies to adopt agroecological practices and should refer to agroecology and sustainable agriculture in national strategies to realise the right to food and national plans to mitigate climate change. Public spending in agriculture needs to be redirected from private goods to providing public goods such as extension services, rural infrastructure and research on agroecological methods. It’s urgent to facilitate the transition to agroecology, a low-carbon, resource preserving, resilient agriculture that can combat hunger, malnutrition and climate change and benefit millions of the world’s poorest farmers.

**Dr Olivier De Schutter was appointed the Special Rapporteur on the right to food in May 2008 by the United Nations Human Rights Council. He is independent from any government or organization.
